# Java 8 Parallel SearchStreamGang Example (Part 2)

Douglas C. Schmidt <u>d.schmidt@vanderbilt.edu</u> www.dre.vanderbilt.edu/~schmidt

Institute for Software Integrated Systems

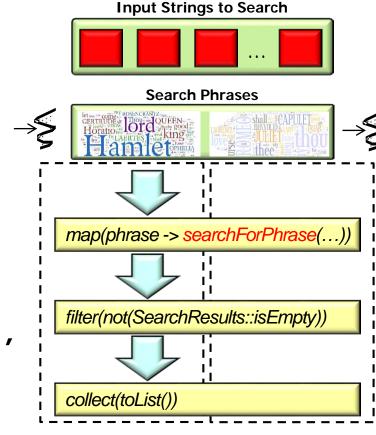

Vanderbilt University Nashville, Tennessee, USA

#### Learning Objectives in this Part of the Lesson

- Know how Java 8 parallel streams are applied in the SearchStreamGang
- Understand the pros & cons of the SearchWithParallelStreams class
- Recognize how a parallel spliterator can improve parallel stream performance

This solution addresses a "con" covered in the first part of this lesson

### Learning Objectives in this Part of the Lesson

- Know how Java 8 parallel streams are applied in the SearchStreamGang
- Understand the pros & cons of the SearchWithParallelStreams class
- Recognize how a parallel spliterator can improve parallel stream performance
- Understand the pros & cons of the SearchWithParallelSpliterator class

<<Java Class>>
SearchWithParallelStreams

- processStream():List<List<SearchResults>>
- processInput(CharSequence):List<SearchResults>

Input Strings to Search SearchWithParallelSpliterator is another <<Java Class>> implementation strategy in the **⊕** SearchStreamGang Search Phrases SearchStreamGang program Horago lord king <<Java Class>> <<Java Class>> SearchWithParallelStreams <<Java Class>≯ <<\Java Class>> ■ SearchWithParallelSpliterator <<Java Class>≯ <<Java Class>> **⊙** SearchWithCompletableFuturesInputs SearchWithParallelStreamInputs <<Java Class>> SearchWithCompletableFuturesPhrases <<Java Class>> SearchWithParallelStreamPhrases

SearchWithParallelSpliterator uses parallel streams in three ways

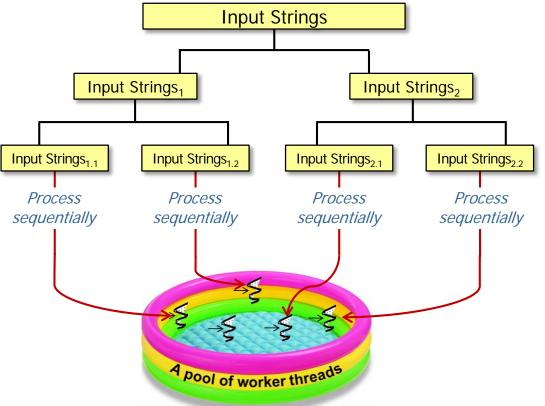

# <<Java Class>> SearchWithParallelSpliterator

- processStream():List<List<SearchResults>>
- processInput(CharSequence):List<SearchResults>

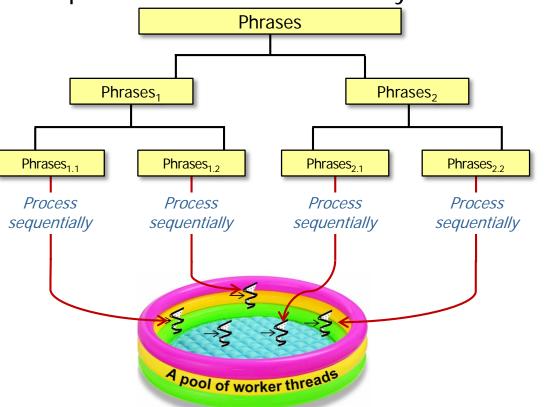

SearchWithParallelSpliterator uses parallel streams in three ways

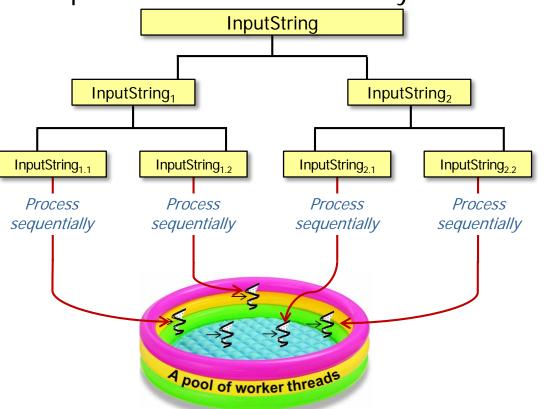

Search chunks of phrases concurrently

- SearchWithParallelSpliterator uses parallel streams in three ways
  - Search chunks of phrases concurrently
  - Search chunks of input concurrently

- SearchWithParallelSpliterator uses parallel streams in three ways
  - Search chunks of phrases concurrently
  - Search chunks of input concurrently
  - Search chunks of each input string concurrently

- SearchWithParallelSpliterator uses parallel streams in three ways
  - Search chunks of phrases concurrently
  - Search chunks of input concurrently
  - Search chunks of each input string concurrently

Time for 38 strings = 703 ms (parallelSpliterator|parallelPhrases|parallelInput)

• The relative contribution of each parallel streams model is shown here:

Time for 38 strings = 706 ms (sequentialSpliterator|parallelPhrases|parallelInput)

Time for 38 strings = 726 ms (parallelSpliterator|sequentialPhrases|parallelInput)

Time for 38 strings = 739 ms (sequentialSpliterator|sequentialPhrases|parallelInput)

Time for 38 strings = 759 ms (parallelSpliterator|parallelPhrases|sequentialInput)

Time for 38 strings = 1760 ms (parallelSpliterator|sequentialPhrases|sequentialInput)

Time for 38 strings = 3000 ms(sequentialSpliterator|sequentialPhrases|sequentialInput)

Time for 38 strings = 749 ms (sequentialSpliterator|parallelPhrases|sequentialInput)

Longer input strings leverage the parallel spliterator even better:

Time for 2 strings = 700 ms (parallelSpliterator|parallelPhrases|parallelInput)

Time for 2 strings = 738 ms (parallelSpliterator|parallelPhrases|sequentialInput)

Time for 2 strings = 760 ms (parallelspliterator parallelPhrases parallelInput)

Time for 2 strings = 761 ms (sequentialSpliterator parallelPhrases parallelInput)

Time for 2 strings = 761 ms (sequential Splitter at or | parallel Phrases | parallel Input)

Time for 2 strings = 1008 ms (parallelSpliterator|sequentialPhrases|parallelInput)

Time for 2 strings = 1008 ms (parallelSpliterator|sequentialPhrases|parallelInput)

Time for 2 strings = 1617 ms (parallelSpliterator|sequentialPhrases|sequentialInput)

Time for 2 strings = 1986 ms (sequentialSpliterator|sequentialPhrases|parallelInput)

Time for 2 strings = 2870 ms (sequentialSpliterator|sequentialPhrases|sequentialInput)

SearchWithParallelSpliterator processInput() has just one minuscule change

```
List<SearchResults> processInput(CharSequence inputSeq) {
  String title = getTitle(inputString);
  CharSequence input = inputSeq.subSequence(...);
  List<SearchResults> results = mPhrasesToFind
    .parallelStream()
    .map(phase ->
         searchForPhrase(phase, input, title, true))
    .filter(not(SearchResults::isEmpty))
    .collect(toList());
                             The value of "true" triggers the use of a
                           parallel search for a phrase in an input string
  return results;
```

 searchForPhrase() uses a parallel spliterator to break the input into "chunks" that are processed in parallel

SearchResults searchForPhrase(String phrase, CharSequence input,

 searchForPhrase() uses a parallel spliterator to break the input into "chunks" that are processed in parallel

StreamSupport.stream() creates a sequential or parallel stream via PhraseMatchSpliterator

 searchForPhrase() uses a parallel spliterator to break the input into "chunks" that are processed in parallel

```
SearchResults searchForPhrase(String phrase, CharSequence input,
                                 String title, boolean parallel) {
  return new SearchResults
    (..., ..., phrase, title, StreamSupport
     .stream(new PhraseMatchSpliterator(input, phrase),
              parallel)
     .collect(toList()));
               The value of "parallel" is true when searchForPhrase()
               is called in the SearchWithParallelSpliterator program
```

See <a href="mailto:docs.oracle.com/javase/8/docs/api/java/util/stream/StreamSupport.html#stream">docs.oracle.com/javase/8/docs/api/java/util/stream/StreamSupport.html#stream</a>

 SearchStreamGang uses PhraseMatchSpliterator that works for both sequential & parallel streams

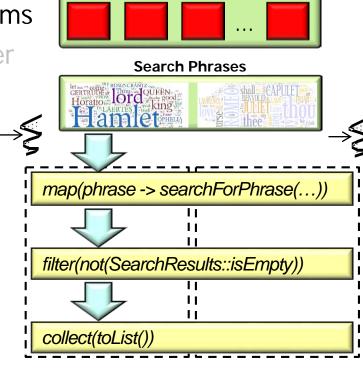

- SearchStreamGang uses PhraseMatchSpliterator that works for both sequential & parallel streams
  - We focused on the sequential portions earlier

- SearchStreamGang uses PhraseMatchSpliterator that works for both sequential & parallel streams
  - We focused on the sequential portions earlier
  - We'll cover the parallel portions now

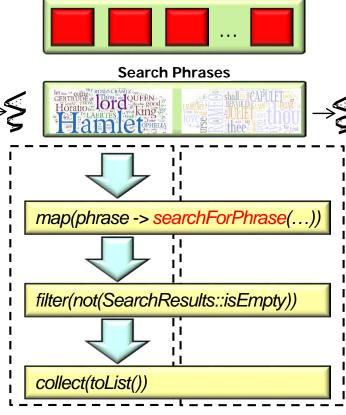

**Input Strings to Search** 

The goal is to further optimize the performance of the parallel streams solution

 Here's the input/output of PhraseMatchSpliterator **Input Strings to Search** for SearchWithParallelSpliterator List **Search Phrases** <String> Stream <String> Stream map(phrase -> searchForPhrase(...)) <SearchResults> Stream filter(not(SearchResults::isEmpty)) <SearchResults> List <SearchResults> collect(toList())

 Here's the input/output of PhraseMatchSpliterator for SearchWithParallelSpliterator

My liege, and madam, to expostulate What majesty should be, what duty is, Why day is day, night is night, and time is time. Were nothing but to waste night, day, and time. Therefore, since brevity is the soul of wit, And tediousness the limbs and outward flourishes, I will be brief. Your noble son is mad. Mad call I it; for, to define true madness, What is't but to be nothing else but mad? But let that go...."

**Input Strings to Search** 

This spliterator splits the input into multiple chunks & searches them in parallel

 Here's the input/output of PhraseMatchSpliterator for SearchWithParallelSpliterator

"... "Brevity is the soul of wit" at [54739]

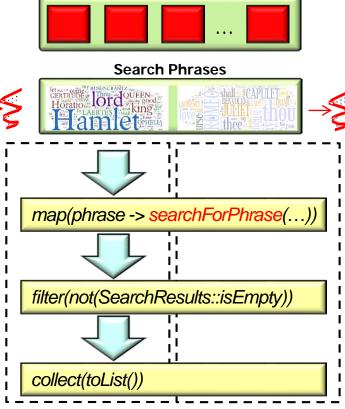

My liege, and madam, to expostulate What majesty should be, what duty is, Why day is day, night is night, and time is time. Were nothing but to waste right, day, and time. Therefore, since brevity is the soul of wit,"

"And tediousness the limbs and outward flourishes, I will be brief. Your noble son is mad.

Mad call I it; for, to define true madness,

What is't but to be nothing else but mad?

But let that go...."

**Input Strings to Search** 

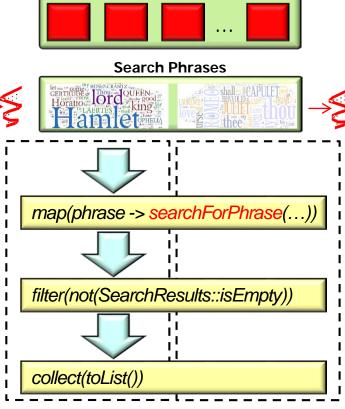

When the split occurs efficiently/evenly the speedups can be substantial!

 Here's the input/output of PhraseMatchSpliterator for SearchWithParallelSpliterator

"... "Brevity is the soul of wit" not found!

My liege, and madam, to expostulate What majesty should be, what duty is, Why day is day, night is night, and time is time. Were nothing but to waste right, day, and time. Therefore, since brevity is the soul of"

"wit, And tediousness the limbs and outward flourishes, I will be brief. Your noble son is mad. Mad call I it; for, to define true madness, What is't but to be nothing else but mad? But let that go...."

**Input Strings to Search** 

However, the spliterator must be careful not to split input across phrases...

 PhraseMatchSpliterator uses Java regex to create a stream of SearchResults Result objects that match the # of times a phrase appears in an input string

```
class PhraseMatchSpliterator implements Spliterator<Result> {
  PhraseMatchSpliterator
                                           Spliterator is an interface that
    (CharSequence input,
     String phrase) { ... }
                                          defines eight methods, including
```

```
tryAdvance() & trySplit()
boolean tryAdvance
  (Consumer<? super Result> action)
```

See SearchStreamGang/src/main/java/livelessons/utils/PhraseMatchSpliterator.java

PhraseMatchSpliterator uses Java regex to create a stream of SearchResults
Result objects that match the # of times a phrase appears in an input string
class PhraseMatchSpliterator implements Spliterator<Result> {

boolean tryAdvance(Consumer<? super Result> action) { ... }
...

Earlier we analyzed several of its methods that are used in sequential streams

 PhraseMatchSpliterator uses Java regex to create a stream of SearchResults Result objects that match the # of times a phrase appears in an input string class PhraseMatchSpliterator implements Spliterator<Result> {

```
Spliterator<Result> trySplit() { ... }
int computeStartPos(int splitPos) { ... }
```

int tryToUpdateSplitPos(int startPos, int splitPos) { ... } PhraseMatchSpliterator splitInput(int splitPos) { ... }

We'll now explore its methods that are used for parallel streams

Note that there is *no* synchronization in any of these methods!!!

PhraseMatchSpliterator uses Java regex to create a stream of SearchResults

Result objects that match the # of times a phrase appears in an input string class PhraseMatchSpliterator implements Spliterator<Result> { Spliterator<Result> trySplit() { if (input is below minimum size) return null else { split input in 2 relatively InputString even-sized chunks trySplit() return a spliterator InputString<sub>1</sub> InputString<sub>2</sub> for "left chunk" trySplit() trySplit() InputString<sub>1</sub> InputString<sub>1,2</sub> InputString<sub>2</sub> InputString<sub>2,2</sub>

trySplit() attempts to split the input "evenly so phrases can be matched in parallel

PhraseMatchSpliterator uses Java regex to create a stream of SearchResults
Result objects that match the # of times a phrase appears in an input string
class PhraseMatchSpliterator implements Spliterator<Result> {

Spliterator<Result> trySplit() { InputString trySplit() InputString<sub>1</sub> InputString<sub>2</sub> trySplit() trySplit() InputStrina<sub>1</sub> InputStrina<sub>1</sub> InputString<sub>2</sub> InputString

Splits don't needn't be perfectly equal in order for the spliterator to be efficient

PhraseMatchSpliterator uses Java regex to create a stream of SearchResults

Result objects that match the # of times a phrase appears in an input string

class PhraseMatchSpliterator implements Spliterator<Result> {

Spliterator<Result> trySplit() { if (mInput.length() <= mMinSplitSize) return null;</pre>

int startPos, splitPos = mInput.length() / 2; if ((startPos = computeStartPos(splitPos)) < 0) return null;</pre>

if ((splitPos = tryToUpdateSplitPos(startPos, splitPos)) < 0)</pre> return null; This code is complicated since it doesn't split a string across a phrase return splitInput(splitPos); ..

This code is highly commented, so please have a look at it (we may cover it later)

 PhraseMatchSpliterator uses Java regex to create a stream of SearchResults Result objects that match the # of times a phrase appears in an input string

```
class PhraseMatchSpliterator implements Spliterator<Result> {
 Spliterator<Result> splitInput(int splitPos) {
    CharSequence seq = mInput.subSequence(0, splitPos);
   mInput = mInput.subSequence(splitPos, mInput.length());
    mPhraseMatcher = mPattern.matcher(mInput);
```

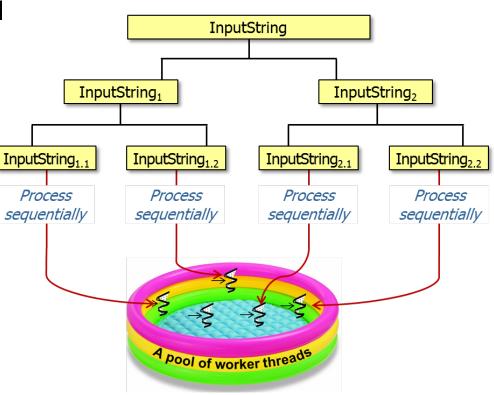

Return a Spliterator that handles "left hand" portion of input, while "this" object handles "right hand" portion of input

return new PhraseMatchSpliterator(seq, ...); ...

• The Java 8 parallel streams runtime processes all the spliterator chunks in

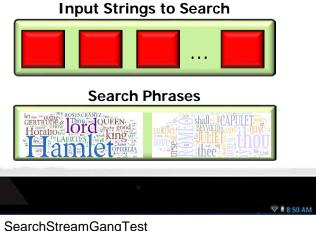

parallel in the common fork-join pool

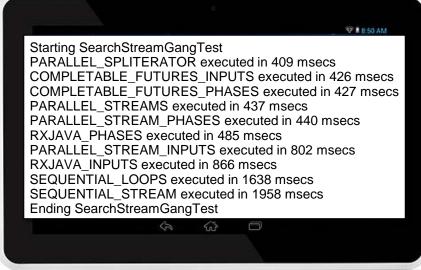

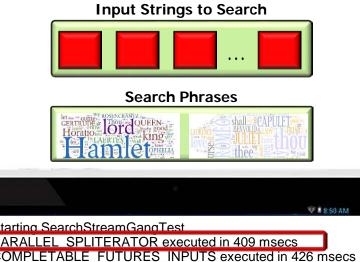

This parallelism is in addition to parallelism of input string & phrase chunks!!

 This example shows how a parallel spliterator can help transparently improve program performance

 This example shows how a parallel spliterator can help transparently improve program performance

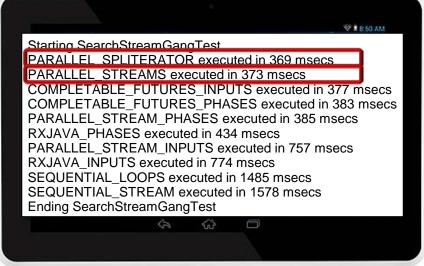

Tests conducted on a 2.7GHz quad-core Lenovo P50 with 32 Gbytes of RAM

 This example shows how a parallel spliterator can help transparently improve program performance

Tests conducted on a 2.9GHz quad-core MacBook Pro with 16 Gbytes of RAM

- This example shows how a parallel spliterator can help transparently improve program performance
  - These speedups occur since the granularity of parallelism is smaller & thus better able to leverage available cores

• This example also shows that the difference between using sequential vs parallel spliterator can be minuscule!

```
SearchResults searchForPhrase(String phrase, CharSequence input,
                                 String title, boolean parallel) {
  return new SearchResults
     (..., ..., phrase, title, StreamSupport
      .stream(new PhraseMatchSpliterator(input,
                                            phrase),
              parallel)
      .collect(toList()));
                  Switching this boolean from "false" to "true" controls
                 whether the spliterator runs sequentially or in parallel
```

• This example also shows that the difference between using sequential vs parallel spliterator can be minuscule!

.collect(toList()));

Of course, it took non-trivial time/effort to create PhraseMatchSpliterator..

• The parallel-related portions of PhraseMatchSpliterator are *much* more complicated to program than the sequential-related portions...

```
class PhraseMatchSpliterator
      implements Spliterator<Result> {
  Spliterator<Result> trySplit() { ... }
  int computeStartPos(int splitPos) { ... }
  int tryToUpdateSplitPos(int startPos,
                          int splitPos)
    { ... }
```

PhraseMatchSpliterator splitInput(int splitPos) { ... }

• The parallel-related portions of PhraseMatchSpliterator are *much* more complicated to program than the sequential-related portions...

```
class PhraseMatchSpliterator
      implements Spliterator<Result> {
  Spliterator<Result> trySplit() { ... }
  int computeStartPos(int splitPos) { ... }
  int tryToUpdateSplitPos(int startPos,
                          int splitPos)
             Must split carefully..
  PhraseMatchSpliterator splitInput(int splitPos) { ... }
```

Junit tests are extremely useful..

• The parallel-related portions of PhraseMatchSpliterator are *much* more complicated to program than the sequential-related portions...

```
class PhraseMatchSpliterator
      implements Spliterator<Result> {
  Spliterator<Result> trySplit() { ... }
  int computeStartPos(int splitPos) { ...
  int tryToUpdateSplitPos(int startPos,
                          int splitPos)
    { ... }
```

Vriting the narallel spliterator took longer than writing the rest of the program

PhraseMatchSpliterator splitInput(int splitPos) { ... }

Writing the parallel spliterator took longer than writing the rest of the program!

# End of Java 8 Parallel SearchStreamGang Example (Part 2)
